

Assignment no 8

PHP Installation Check

First, open Command Prompt and type the following command:

```
php -v
```

This command is used to check whether PHP is installed on the system or not.

After that, open the Xampp/php folder and copy its path. Then open **Environment Variables** and add the copied path by clicking on the **New** option. Save the changes by clicking **OK**.

Now open Command Prompt again and run:

```
php -v
```

If the PHP version is displayed successfully, it means PHP is configured properly. Otherwise, repeat the same process again.

Composer Installation

To install Composer, search for **Composer PHP** in a web browser and open the official website. Download the installer file and run it.

During installation, allow all required permissions and continue by clicking on the **Next** button. Finally, click on **Finish** to complete the setup.

After installation, verify Composer by running the following command in Command Prompt:

```
composer -v
```

If the Composer version appears, the installation is successful.

Laravel Installation

Open the official Laravel website and copy the installation command:

```
composer global require laravel/installer
```

Paste this command into Command Prompt and execute it.

Next, create a new folder on the Desktop, for example my_app. Open this folder and launch Command Prompt from that location.

To create a Laravel project, run the following command:

```
laravel new my_app
```

This command creates a new Laravel application.

Node.js Installation

Visit the official Node.js website and download the installer.

Run the installer, allow permissions, and complete the installation process by clicking **Next** and **Finish**.

After installation, verify Node.js and NPM by using these commands:

```
node -v
```

`npm -v`

If both versions are displayed, the installation is completed successfully.

PHP.ini File Configuration

Open the `php.ini` file in Visual Studio Code.

Press `Ctrl + F` and search for the following line:

`extension=zip`

Remove the semicolon (;) before this line to enable the ZIP extension.

Then open Command Prompt and type:

`php -m`

If the ZIP extension appears in the list, the configuration is successful. If it does not appear, repeat the process and make sure PHP version 8.2 is installed.

Creating a New Laravel Project

Go to the `xampp/htdocs` folder and open Command Prompt there.

Run the following command:

`laravel new my_app`

During project creation, select the following options:

- Starter Kit : None
- Testing Framework : 0
- AI-assisted Coding : No
- Database : MySQL
- Default Database Update : Yes
- Ignore Scripts : Yes

After completing the setup, Laravel will display the following commands:

`cd my_app`

`composer run dev`

Open a browser and search:

`localhost:8000`

If the Laravel welcome page opens, the project has been created successfully.
